

**APPARATUS AND METHOD FOR PROVIDING ACCESS TO A DATA  
STREAM BY A PLURALITY OF USERS AT A SAME TIME**

**BACKGROUND OF THE INVENTION**

5

**1. Technical Field:**

The present invention is directed to an apparatus and method for providing access to a data stream by a plurality of users at a same time. In particular, the present invention is directed to an apparatus and method for data stream splitter management for multiplexing access by a plurality of users to the same data stream.

**2. Description of Related Art:**

Presently, in distributed data processing systems, when a user is involved in a session making use of system resources, the session is typically set up so that a single user has access to the system resource during the session. Thus, only a single user is able to make use of the system resource until the session is completed and the system resource is released for use by another user.

Recently, systems have been devised for allowing multiple users to monitor the status of a system resource in a single session. Typically, in these systems, one user has full access to the system resources and is provided with the ability to use and/or modify these system resources. The other users involved in the session act as observers only and are not provided with full access to the system resources.

In either of the above systems, a problem arises if a first user wishes to share modifications to a system resource with a second user, and the second user wishes

to share modifications with the first user. Each user must gain access to the system resource, make their modifications, release access to the system resource and then allow the other user to gain access and make their modifications. The first user must then re-access the system resource to inspect the modifications of the second user. (There is no mechanism by which both users can have full access to the system resource at approximately the same time.)

10           Thus, it would be beneficial to have an apparatus  
and method whereby a plurality of users are provided full  
access to the same system resource in a same session at  
approximately a same time and be able to share the  
results of each user's access to the system resource with  
15 other users in the session.

[illegible]

**SUMMARY OF THE INVENTION**

5 The present invention provides an apparatus and  
method for providing full access to a data stream by a  
plurality of users at approximately a same time. The  
apparatus and method include a data stream splitter  
manager that listens for new connections from client  
devices. When a new connection from a client device is  
10 identified, the data stream splitter manager generates a  
pseudo-terminal for the client device and adds the client  
device and pseudo-terminal information to a data stream  
splitter table. In addition, if a data stream splitter  
is not already established for handling data transfer  
15 between the data stream splitter manager and a requested  
resource, a new data stream splitter may be generated to  
handle the data transfer.

20 Thereafter, the data stream splitter associated with  
the system resource searches the data stream splitter  
table for client devices that are sharing access to the  
system resource. The data stream splitter sends data  
from the data stream associated with the system resource  
to the pseudo-terminals associated with the client  
devices that are currently sharing the system resource in  
25 a sequential manner. Similarly, the data stream  
splitter receives input from the client devices via the  
pseudo-terminals and sends the input to the data stream  
associated with the system resource. In this way, each  
client device has an individual connection to the system  
30 resource but the output from the system resource is  
shared by each of the client devices. Additionally, each  
client device is provided with the output from the system  
resource in a realtime manner.

Docket No. AUS9-2000-0257-US1

Other features and advantages of the present invention will be described in, or will become apparent, to those of ordinary skill in the art in view of the figures and the following detailed description of the preferred embodiments.

5

**BRIEF DESCRIPTION OF THE DRAWINGS**

The novel features believed characteristic of the invention are set forth in the appended claims. The invention itself, however, as well as a preferred mode of use, further objectives and advantages thereof, will best be understood by reference to the following detailed description of an illustrative embodiment when read in conjunction with the accompanying drawings, wherein:

**Figure 1** is a diagram illustrating a distributed data processing system according to the present invention;

**Figure 2** is an exemplary block diagram of a server according to the present invention;

**Figure 3** is an exemplary block diagram of a client according to the present invention;

**Figure 4** is an exemplary block diagram of the principle elements of a server in accordance with the present invention;

**Figure 5** is an exemplary diagram illustrating an exemplary implementation of the present invention;

**Figures 6A and 6B** are flowcharts outlining an exemplary operation of the present invention; and

**Figure 7** is an illustration of a display of a data stream from a client device implementing the present invention.

**DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS**

With reference now to the figures, and in particular  
5 with reference to **Figure 1**, a pictorial representation of  
a distributed data processing system is depicted in which  
the present invention may be implemented. Distributed  
data processing system **100** is a network of computers in  
which the present invention may be implemented.

10 Distributed data processing system **100** contains network  
**102**, which is the medium used to provide communications  
links between various devices and computers connected  
within distributed data processing system **100**. Network  
**102** may include permanent connections, such as wire or  
15 fiber optic cables, or temporary connections made through  
telephone connections.

In the depicted example, server **104** is connected to  
network **102**, along with storage unit **106**. In addition,  
clients **108**, **110** and **112** are also connected to network  
20 **102**. These clients, **108**, **110** and **112**, may be, for  
example, personal computers or network computers. For  
purposes of this application, a network computer is any  
computer coupled to a network which receives a program or  
other application from another computer coupled to the  
25 network. In the depicted example, server **104** provides  
data, such as boot files, operating system images and  
applications, to clients **108-112**. Clients **108**, **110** and  
**112** are clients to server **104**. Distributed data  
processing system **100** may include additional servers,  
30 clients, and other devices not shown.

In the depicted example, distributed data processing

system **100** is the Internet, with network **102** representing a worldwide collection of networks and gateways that use the TCP/IP suite of protocols to communicate with one another. At the heart of the Internet is a backbone of high-speed data communication lines between major nodes or host computers consisting of thousands of commercial, government, education, and other computer systems that route data and messages. Of course, distributed data processing system **100** also may be implemented as a number of different types of networks such as, for example, an intranet or a local area network. **Figure 1** is intended as an example and not as an architectural limitation for the processes of the present invention.

Referring to **Figure 2**, a block diagram of a data processing system which may be implemented as a server, such as server **104** in **Figure 1**, is depicted in accordance with the present invention. Data processing system **200** may be a symmetric multiprocessor (SMP) system including a plurality of processors **202** and **204** connected to system bus **206**. Alternatively, a single processor system may be employed. Also connected to system bus **206** is memory controller/cache **208**, which provides an interface to local memory **209**. I/O bus bridge **210** is connected to system bus **206** and provides an interface to I/O bus **212**. Memory controller/cache **208** and I/O bus bridge **210** may be integrated as depicted. Peripheral component interconnect (PCI) bus bridge **214** connected to I/O bus **212** provides an interface to PCI local bus **216**. A number of modems **218-220** may be connected to PCI bus **216**. Typical PCI bus implementations will support four PCI expansion slots or add-in connectors. Communications

links to network computers **108-112** in **Figure 1** may be provided through modem **218** and network adapter **220** connected to PCI local bus **216** through add-in boards. Additional PCI bus bridges **222** and **224** provide interfaces for additional PCI buses **226** and **228**, from which additional modems or network adapters may be supported. In this manner, server **200** allows connections to multiple network computers. A memory mapped graphics adapter **230** and hard disk **232** may also be connected to I/O bus **212** as depicted, either directly or indirectly.

Those of ordinary skill in the art will appreciate that the hardware depicted in **Figure 2** may vary. For example, other peripheral devices, such as optical disk drives and the like, also may be used in addition to or in place of the hardware depicted. The depicted example is not meant to imply architectural limitations with respect to the present invention. The data processing system depicted in **Figure 2** may be, for example, an IBM RISC/System 6000, a product of International Business Machines Corporation in Armonk, New York, running the Advanced Interactive Executive (AIX) operating system.

With reference now to **Figure 3**, a block diagram of a data processing system in which the present invention may be implemented is illustrated. Data processing system **300** is an example of a client computer. Data processing system **300** employs a peripheral component interconnect (PCI) local bus architecture. Although the depicted example employs a PCI bus, other bus architectures, such as Micro Channel and ISA, may be used.

Processor **302** and main memory **304** are connected to PCI local bus **306** through PCI bridge **308**. PCI bridge **308**

may also include an integrated memory controller and cache memory for processor **302**. Additional connections to PCI local bus **306** may be made through direct component interconnection or through add-in boards. In the

5 depicted example, local area network (LAN) adapter **310**, SCSI host bus adapter **312**, and expansion bus interface **314** are connected to PCI local bus **306** by direct component connection.

In contrast, audio adapter **316**, graphics adapter

10 **318**, and audio/video adapter (A/V) **319** are connected to PCI local bus **306** by add-in boards inserted into expansion slots. Expansion bus interface **314** provides a connection for a keyboard and mouse adapter **320**, modem **322**, and additional memory **324**.

15 In the depicted example, SCSI host bus adapter **312** provides a connection for hard disk drive **326**, tape drive **328**, CD-ROM drive **330**, and digital video disc read only memory drive (DVD-ROM) **332**. Typical PCI local bus implementations will support three or four PCI expansion

20 slots or add-in connectors.

An operating system runs on processor **302** and is used to coordinate and provide control of various components within data processing system **300** in **Figure 3**. The operating system may be a commercially available

25 operating system, such as OS/2, which is available from International Business Machines Corporation. "OS/2" is a trademark of International Business Machines Corporation.

An object oriented programming system, such as Java, may run in conjunction with the operating system,

30 providing calls to the operating system from Java programs or applications executing on data processing

system **300**. Instructions for the operating system, the object-oriented operating system, and applications or programs are located on a storage device, such as hard disk drive **326**, and may be loaded into main memory **304** for execution by processor **302**.

Those of ordinary skill in the art will appreciate that the hardware in **Figure 3** may vary depending on the implementation. For example, other peripheral devices, such as optical disk drives and the like, may be used in addition to or in place of the hardware depicted in **Figure 3**. The depicted example is not meant to imply architectural limitations with respect to the present invention. For example, the processes of the present invention may be applied to multiprocessor data processing systems.

The present invention provides a mechanism by which a plurality of users, such as users of client devices **108**, **110** and **112**, may obtain full access to a system resource during a same session. Using the present invention, a user on a first client device may have full access to the same data stream as another user on a second client device during the same session. Furthermore, each user may add to the data stream as he/she sees fit and have their additions to the data stream shared with each of the users that are accessing the data stream during that session. Thus, with the present invention, each client device may have a private communication channel to the system resource which is not accessible by other client devices while the output from the resource is shared by all of the client devices participating in a session.

In order to provide the mechanism set forth above, a

server, such as server 104, implements a data stream splitter manager and one or more data stream splitters.

**Figure 4** is an exemplary block diagram illustrating the primary elements of a server in accordance with the present invention. As shown in **Figure 4**, the server includes an input/output interface **410**, a data stream splitter manager **420**, a plurality of data stream splitters **430-450**, a data stream splitter table storage device **460**, and a buffer **470**. These elements are shown being coupled via a signal/data bus **480**, however any other mechanism for coupling these elements may be utilized without departing from the spirit and scope of the present invention. The elements **410-470** may be implemented as hardware, software, or a combination of hardware and software without departing from the spirit and scope of the present invention.

The data stream splitter manager <sup>420</sup>~~430~~ manages client device's access to the one or more data stream splitters. Each data stream splitter **430-450** handles a particular data stream to which the client devices may have access. The data stream splitters may be dynamically constructed/desconstructed as needed. For example, if a new session is initiated with a system resource that is not currently being handled by an existing data stream splitter, a new data stream splitter may be constructed to facilitate sharing of the data stream to and from the system resource. Similarly, once a session has ended, the data stream splitter for that session may be deconstructed if no longer needed.

While the preferred embodiments of the present invention will be described in terms of each data stream splitter **430-450** handling a single data stream, it is

[illegible]

Data Entry

In the case where a large data stream splitter table is used, only those pseudo-terminals associated with entries in the data stream splitter table identified as requesting access to the data stream handled by the data stream splitter will be provided access to the data stream. Other entries in the large data stream splitter table will not be provided access to the data stream if they are not marked for attachment to that specific data stream. In the case where individual tables are being

used for each data stream splitter, all of the pseudo-terminals associated with entries in the table will be provided access to the data stream in the manner set forth above.

5 In addition to sending the data stream to the client devices, the data stream splitter manager 420 receives input from the client devices and applies the input to the corresponding pseudo-terminal in accordance with the data stream splitter table in the data stream splitter *feedback*

10 table storage device 460. The results of a client device's input to the pseudo-terminal are then applied to the data stream and transmitted to each of the client devices participating in the session when the data stream splitter cycles through the entries in the data stream splitter table. *in the data stream from page* *important*

15 In this way, each client device has full access to modify the data stream with the results of the modification being sent to each of the other client devices participating in the session.

In a preferred embodiment, the above process is

20 implemented on a character by character basis. For example, as a user of a client device types input to the data stream, each character typed is sent to the system resource for that data stream. In response, the system resource generates an output. The output from the system

25 resource is immediately sent, via the data stream, to each of the client devices requesting access to the data stream in a sequential and cyclical manner. *important*

Thus, if a first user is typing a command into his/her client device, each character is sent to the

30 system resource via the data stream. The system resource generates an output of a graphical character associated with the particular character input from the first user.

Docket No. AUS9-2000-0257-US1

This output is sent to each of the other client devices requesting access to the data stream. Thus, all of the client devices in the session will see the first user typing the command as if the first user were typing the command directly using the particular client device. In this way, each user is provided with a realtime output from the system resource based on the input received from the other users and him/herself.

Client devices can join existing sessions via the data stream splitter manager 420 by requesting access to the same system resource that is being access by another client device in an established session. When a client device joins an existing session, the client device information, pseudo-terminal information, and data stream splitter information is added to the data stream splitter table maintained by the data stream splitter manager 420 in the data stream splitter table storage device 460. Thereafter, the newly added client device is provided with full access to the data stream for that session.

In addition, the data stream splitter manager may include a buffer 470 of data from the data stream. This buffer 470 may store, for example, a predetermined amount of data obtained from the data stream for a past predetermined period of time. For example, the buffer 470 may store data obtained from the data stream for the past minute of session time. When a new client device joins the session, the new client device may be provided with this buffered data to provide a context by which the new client device can being joining in the session. The data in the buffer 470 may be continuously updated when the buffer 470 becomes full. Thereby, old data in the buffer 470 is cycled out, e.g., overwritten, when new

2025-04-23 10:00:00

Sub B1

~~data is received.~~

**Figure 5** is a block diagram illustrating an implementation of the present invention. As shown in **Figure 5**, a plurality of client devices **510-540** are involved in a number of sessions. Each client device **510-540** is capable of being a participant in a plurality of sessions. The sessions shown in **Figure 5** are implemented as "windows," which herein refers to a view port through which software is run under any operating system.

Each session is managed by one of the data stream splitter managers **550** and **560** and is handled by one of the data stream splitters **570-595**. Each data stream splitter **570-595** sends and receives data along one data stream, e.g., data stream 1, 2, 3 or 4.

In the specific example shown in **Figure 5**, there is one bi-directional input/output data stream per line between two entities. The data streams 1-4 are any data streams which would normally, in prior art systems, send output to and receive input from a single client device. These data streams may be, for example, data streams consisting of input/output to a debug application, a document editor, an application trace program, or any other type of system resource which may send output to a client device and/or receive input from a client device.

As shown in **Figure 5**, the client device **510** is involved in three sessions, all being managed by data stream splitter manager **550**. Each session is implemented as a pseudo-terminal in the data stream splitter manager, i.e. window A1, A2 and A3, and is handled by a different data stream splitter **570**, **580** and **590**, respectively. Client devices **530** and **540** are likewise involved in a

plurality of sessions being managed by data stream splitter manager 550 and 560. Client device 520 is involved in two sessions, window B1 and window B2, and is attempting to join a third session, window B3.

5 Thus, the data stream 1 is shared by client devices 510 and 520. The data stream 2 is being accessed by only client device 510. The data stream 3 is being shared by all four client devices 510-540. Data stream 4 is being shared by client devices 530 and 540, with client device  
10 520 attempting to share data stream 4.

In the case of client device 520, the client device attempts to join a session to share data stream 4 by connecting to a known port on server 2, on which data stream splitter manager 560 is operating. The data  
15 stream splitter manager 560 forks a copy of itself, i.e. creates an additional instance of the currently running code, described more fully hereafter, to handle input/output to the client device 520 window B3. The data stream splitter manager 560 also opens a  
20 pseudo-terminal for communication with data stream splitter 595, which is already handling input/output between data stream 4 and windows C2 and D2 of client devices 530 and 540.

The forked copy of the data stream splitter manager  
25 560 then sets elements in the data stream splitter table to let the data stream splitter 595 know on what pseudo terminal the data stream splitter manager 560 will be communicating for the client device. When the data stream splitter 595 cycles through the entries in the  
30 data stream splitter table, the data stream splitter 595 sends data stream 4 output to the various windows C2, D2

006644-04300

☆

input

Fix

and B3. The data stream splitter **595** also sends any input from the windows C2, D2 and B3 to the data stream 4. Should any of the client devices **510-540** disconnect from the data stream splitter manager **560**, the data stream splitter table will be updated accordingly by removing the entry for that pseudo-terminal and thus, the data stream splitter **595** will stop sharing the data stream 4 with that client device.

Furthermore, in an alternative embodiment, the data stream splitter manager **560** may maintain a data stream splitter table for a data stream splitter and a particular data stream even if all of the client devices involved in the session disconnect from the data stream splitter manager **560**. This maintaining of the data stream splitter table may be performed for a predetermined period of time, or may be maintained indefinitely until a command to logically remove the session from the data stream splitter table is received from a client device or network administrator, depending on the particular system requirements. In this way, all of the client devices may disconnect, such as at the end of a work day, and resume the session at a later time.

The data stream splitter manager of the present invention may be implemented as an application running on a server that is either apparent or unapparent to the client devices. For example, the data stream splitter manager may be implemented as an application used by a client device or may be implemented as a daemon process on a server that receives data from the client device and processes the data without the user of the client device being made aware of the presence of the data stream splitter manager.

10           In summary, in a particular embodiment of the  
present invention described above, the data stream  
splitter manager **560** listens for new connection requests  
from client devices, for example, on a known network  
port. When a connection is made from a client device,  
15   the data stream splitter manager **560** forks a copy of the  
currently running code, i.e. the data stream splitter  
manager **560**, and returns to listening for the next new  
connection.

The forked copy of the data stream splitter manager 560, hereafter referred to as the client-specific server, may perform the following functions. The client-specific server exchanges/verifies software versions between the client device and the server and verifies any optional security information. This may include making sure the connecting client device hostname is authorized, making sure the connecting client device username is authorized, prompting for and accepting/rejecting a password, making sure the system resource to be shared is authorized to be accessible by the client device, changing the username to upgrade/downgrade authority, changing a group name to upgrade/downgrade authority, and the like.

The client-specific server may further handle

command flag and menu requests to start a new data stream splitter, join an existing data stream splitter, look for a system resource already being multiplexed and then join a data stream splitter or start a new one as appropriate, 5 leave a current data stream splitter, report on current connections, quit a connection, and the like. Moreover, the client-specific server pipelines communication from data stream splitter code to client devices by reading data read from the pseudo terminals specific to this 10 unique combination of data stream splitter and client-specific server, then writing the same data over sockets network protocol to the client devices. Additionally, the client-specific server pipelines communication from client devices to data stream splitter 15 code by reading data form the client devices over the sockets network protocol and then writing the same data to the pseudo terminals specific to this unique combination of data stream splitter and client specific server.

20       The data stream splitter, such as data stream splitter 595, uses non-blocking raw input so that any data from any connected client device will go directly to the data stream without any delay waiting for other client devices and without filtering any particular bit 25 patterns, such as escape sequences. By the term "non-blocking" what is meant is that there is no processing of the input by the client device prior to the input being sent to the data stream. Thus, as a user types a character on the client device, this character is 30 immediately sent to the data stream without waiting for the user to select a transmit function, press the "Enter" button, or the like. In this way, each client device

participating in a session will be provided with realtime output from the system resource based on inputs received by the system resource from each of the client devices.

5 The data stream splitter accesses the particular system resource by redirecting input and output to and from that system resource through a single point to single point communication path. The data stream splitter records streamed data coming out of the system resource into a playback buffer so the data stream  
10 splitter can still be "seen" by clients who were not connected in time to see the output "live" at the time the system resource sent it. Additionally, the data stream splitter continually scans the data stream  
splitter table and connects those client devices  
15 requesting to be connected, disconnects those client devices requesting to be disconnected, sends any data not yet sent to a client device from the multiplexed data stream to that client device using the pseudo-terminal for that client device, sends any data not yet sent to  
20 the multiplexed data stream from the client device to the multiplexed data stream, and optionally exits when the number of connected client devices connected reaches zero.

Thus, with the present invention, the data stream  
25 splitter manager spawns copies of itself as  
client-specific servers on an as needed basis. *important*  
Similarly, the client-specific servers spawn data stream  
splitters on an as needed basis. The client device  
communicates with the data stream splitter manager just  
30 long enough for the data stream splitter manager to  
create a client-specific server for that client device.  
Thereafter, the client device relays communication

between the user and the client-specific server over the network.

As described above, the present invention provides a mechanism through which a plurality of client devices may share the same data stream and have full access to modify the shared data stream. In addition, the present invention provides a mechanism by which modifications made by one client device to a data stream are transmitted to all other client devices active during a session.

**Figure 6A** is a flowchart outlining an exemplary operation of a data stream splitter manager of the present invention when starting/joining a session to share a data stream. As shown in **Figure 6A**, the operation begins with a request for access to a data stream being received (step **610**). A pseudo-terminal is created for the client device (step **620**). An entry in the data stream splitter table for the requested data stream is added identifying the client device and the pseudo-terminal (step **630**). Thereafter, the data stream splitter manager sends any new data from the client device to the pseudo-terminal (step **640**) and any new data from the pseudo-terminal to the client device (step **650**).

The data stream splitter manager monitors for a disconnect from the client device (step **660**) and if the client device disconnects, removes the entry in the data stream splitter table for the client device (step **670**). Otherwise, if the client device does not disconnect, the data stream splitter manager returns to step **640**.

**Figure 6B** is a flowchart outlining an exemplary operation of a data stream splitter of the present invention when sending/receiving data to and from a data

The multiplexer sends data from the data stream to the pseudo-terminal associated with the entry from the data stream splitter table (step 720). Thereafter, the data stream splitter sends any input from the pseudo-terminal to the data stream (step 730). The data stream splitter then reads the next entry in the data stream splitter table (step 740) and returns to step 720.

**Figure 7** illustrates an example display from a client device of a shared session for a data stream. The particular application of the present invention shown in **Figure 7** is to a debug session for debugging a computer program. However, one of ordinary skill in the art will appreciate that the present invention is not limited to any particular type of data stream. Rather, the present invention may be applied to any type of data stream including, audio, video, textual data streams and the like.

As shown in **Figure 7**, the display includes a first listing of debug information with an identifier that the debugger has been entered via keyboard. Thereafter, a conversation commences between two users, using two different client devices. The conversation is facilitated by the command prompt of the debugger application. Thus, because the textual comments of the

The users are discussing the debug information previously displayed. Each user has access to the data stream such that each user sees on his/her client device the debug information as well as the comments from the other user and the error messages. Thus, each user has complete access to modify the data stream and is provided with the modifications entered by other users.

10           The comments from the two users are displayed as the  
user types them. In other words, the output seen by the  
users is raw output from the system resource. As a  
result, if a first user mistypes a command and backspaces  
to correct the command, the second user will see the  
15   typing of the mistyped command and the backspacing as it  
occurs. Similarly, if both users are typing commands at  
the same time, the result will be a garbled command  
interleaving both inputs from the users. Thus, the  
present invention provides a mechanism by which both  
20   users have complete and full access to the data stream at  
approximately the same time. Each user is provided with  
a realtime display of the modified data stream based on  
the inputs from the other user and him/herself.

As described above, the present invention provides an apparatus and method for providing a plurality of client devices shared access to a data stream, and thus, to system resources accessed during a session. This shared access allows each user to modify the data stream and be provided with other user's modifications to the data stream.

It is important to note that while the present invention has been described in the context of a fully

functioning data processing system, those of ordinary skill in the art will appreciate that the processes of the present invention are capable of being distributed in the form of a computer readable medium of instructions and a variety of forms and that the present invention applies equally regardless of the particular type of signal bearing media actually used to carry out the distribution. Examples of computer readable media include recordable-type media such a floppy disc, a hard disk drive, a RAM, CD-ROMs, and transmission-type media such as digital and analog communications links.

The description of the present invention has been presented for purposes of illustration and description, and is not intended to be exhaustive or limited to the invention in the form disclosed. Many modifications and variations will be apparent to those of ordinary skill in the art. The embodiment was chosen and described in order to best explain the principles of the invention, the practical application, and to enable others of ordinary skill in the art to understand the invention for various embodiments with various modifications as are suited to the particular use contemplated.
